CSE 1203

Object Oriented Programming [C++]

Chapter 5:
Java Programming -01

Java: Introduction

What is UML?

Java is a popular object oriented programming language, created in 1995.
It is owned by Oracle, and more than **3 billion** devices run Java.
It is used for:
- Mobile applications (specially Android apps)
- Desktop applications
- Web applications
- Web servers and application servers
- Games
- Database connection
- And much, much more!

Java Specification:
java syntax & semantic

– To write English we should follow some rules (Grammar, …).

– Also, to write Java we should follow some rules → syntax & semantics.

– He are playing → syntax error. (Grammar)
– He is hello and bye → semantic error. (Meaning)

API: Application Programming Inter

– Also known as a 'library'.

– Contains predefined Java code that we can use to develop Java programs.
   → Faster and easier development process | no need to write everything from scratch.

Java Editions: 3 types

– Java Standard Edition (SE): develop applications that run on desktop.

– Java Enterprise Edition (EE): develop server–side applications.

– Java Micro Edition (ME): develop applications for mobile devices.

JDK: Java Development Kit

– Set of programs that enable us to develop our programs.

– Contains JRE (Java Runtime Environment) that is used to run our programs.

– JRE & JDK contain JVM (Java Virtual Machine).

– JVM executes our java programs on different machines.
   → java is independent .

Java: Introduction

IDE: Integrated Development Environment

A program that allows us to:
- Write | source code.
- Compile | machine code.
- Debug | tools to find errors.
- Build | files that can be executed by JVM.
- Run | execute our program.

→ Development is faster and easier.

Popular Java IDEs: NetBeans, Eclipse, IntelliJ IDEA, …

Java: Basic Concepts

⭐ Classes & Objects

⭐ Methods

⭐ Naming Conventions

⭐ Java Program Structure

⭐ Packages

Java: Class Structure

```
class class_name {
    code block
}
```

Java : Methods

```
return_type method_name( parameters ) {
    code block
}
```

Note: every method is written inside a Class.
→ A class is a container of methods.

Java : Method Calling

```
method_name( give parameters );
```

→ The code block of this method will be executed.

Note: the main() method is automatically called when we run our java program.
→ it is the first method that is called.
→ it is the starting point of execution of our program

Java: Introduction

Java: Naming Convension

Pascal case convention:
→ `ThisIsAName`
  (class Name)
Camel case convention:
→ `thisIsAName`
  (variable, Method Name)
Snake case convention:
→ `this_is_a_name`

ESO ACADEMY

Java: Programming Structure

```java
public class Main {

    public static void main(String[] args) {

    }

}
```

Note: Each java program must have a class that contain **main()** method

Java : Package

A container for Classes

package
class
methods

Java: println() method

```java
System.out.println("hello");
System.out.println("123");
System.out.println("");
System.out.println("456");
```
→
```
hello
123

456
```

Java : System.out

– `out` is an object of the 'PrintStream' Class.

– `out` has the `print()` and `println()` methods.
  → use '.' to access `print()`/`println()` of `out`.

– `out` refers to the standard output device. (Screen)

– `System` is a Class (pascal case).

– `out` is inside `System` (field).
  → use '.' to access `out` of `System`.

→ `System.out.println()`.

ESO ACADEMY

Java: Introduction

Java: Compiling

```
class Simple{
public static void main(String args[]){
System.out.println("Hello");
}}
```
Hard.java → compiler → Bytecode
                           Simple.class

Compiled by / Generates

Main.java – Source code → Java compiler → Main.class –java bytecode –executable file → by → JVM

Executed With
Library code

Java Virtual Machine, or JVM, loads, verifies and executes Java bytecode. It is known as the interpreter or the core of Java programming language because it executes Java programming.

Java: Program

Program 1: print a message/text

```
package CSE1203;

public class First {
 public static void main(String[] args) {
  System.out.print("Welcome to Java World");
 }
}
```

Output

```
Welcome to Java World
```

Notes: The class name must be the same as the .java source filename and package should be declared at first

Program 2: print a message/text

```
package CSE1203;
public class Second {
 public static void main(String[] args) {
  System.out.print("Talk less listen more");
 }
}
```

Notes: A class Second is created under package CSE1203

Program 2 (ex): call main() of second

```
package CSE1203;
public class First {
 public static void main(String[] args) {
 System.out.println("Welcome to Java World");
 Second.main(null);
 }
}
```

Output

```
Welcome to Java World
Talk less listen more
```

Notes: In the First class just write the class name if you want to call other classes method

Java: Program

Program 2 (ex): change Second class

```
package CSE1203;
public class Second {
 public static void main(String[] args) {
   System.out.println("Talk less listen more");
   Display();
}
public static void Display() {
 System.out.println("Honesty is the best policy");
}
}
```

Output

```
Welcome to Java World
Talk less listen more
Honesty is the best policy
```

Notes: From First class, main() of Second class is called and inside the main() of Second, Display method is called

Access Modifier: 4 Types

1. public : access from everywhere
2. private: access only inside the class
3. protected: access from everywhere
4. default: access from everywhere

Access Modifier: public

The access level is everywhere.
– Inside a class.
– Outside a class.
– Inside the package.
– Outside the package.

Non-Access Modifier: static

You can access fields/methods using the class name.

Example:
System.out
→ out is a static field of System

Java: Program

Program 3: private method

```
package CSE1203;
public class Second {
 public static void main(String[] args) {
  System.out.println("Talk less listen more");
  Display();
 }
 private static void Display() {
  System.out.println("Honesty is the best policy");
 }
}
```

Output

```
Talk less listen more
Honesty is the best policy
```

Notes: It is run from Second but in the following it is run from First. It produces error as Display() is private to Second class

```
package CSE1203;
public class First {
 public static void main(String[] args) {
 System.out.println("Welcome to Java World");
 Second.Display());
 }
}
```

Program 4: static method

```
package CSE1203;
public class Second {
 public static void main(String[] args) {
  System.out.println("Talk less listen more");
  Second.Display();
 }
 private static void Display() {
  System.out.println("Honesty is the best policy");
 }
}
```

Notes: static method can be called by its class name with (.) operator. But if you remove the static from Display() in the following then it can not be called from main(). Remember that a non-static method can not be called from a static method

```
package CSE1203;
public class Second {
 public static void main(String[] args) {
  System.out.println("Talk less listen more");
  Display(); //produces error
 }
 Private void Display() {
  System.out.println("Honesty is the best policy");
 }
}
```

Java: Program

Programming Style

```
public class Main {
    public static void main(String[] args) {
        System.out.println("hello");
    }
}
```
→ Good

```
public class Main {public static void main(String[] args)
{System.out.println("hello");}}
```
→ Bad

Notes: Use proper spacing and indentation

Programming Style : block

```
public class Main {
    public static void main(String[] args) {
        System.out.println("hello");
    }
}
```
→ End-of-line style
Used in java API
Source code

```
public class Main
{
    public static void main(String[] args)
    {
        System.out.println("hello");
    }
}
```
→ Next-line style

Data Types: primitives
byte, short, int, long, float, double, and char are primitive types

```
public static void main(String[] args) {
    int i = 15;
    char c = 'a';
}
```

i | 15 | 300
     | |
c | 'a' | 604

Data Types: reference

```
public static void main(String[] args) {
    String s = "hello";
}
```

s | 1004 | 800
     | |
     | "hello" | 1004

The variable contains the address of the value.
The variable references the value.
s ⟶ "hello"

string class: few methods

|		
charAt()	isEmpty()	toLowerCase()
compareTo()	length()	toUpperCase()
concat()	replace()	toString()
equals()	substring()	trim()

Java: Program

Primitive vs Reference Types

```java
public static void main(String[] args) {
    int i1 = 5;
    int i2 = i1;

    String s1 = "hello";
    String s2 = s1;
}
```

Immutable Objects: primitives

Objects whose contents can not be changed

– A constant is a variable whose value can not change

– An immutable object is an object whose content can not be changed

– Immutable objects are created from immutable classes

– The String Class in Java is Immutable
  → The content of String objects in Java can not be changed

Memory Allocation

i1	5	100
s2	1008	500
i2	5	200
s1	1008	300
"hello"	1008

i1 5
i2 5

s1
s2 → "hello"

Immutable class: string class

```java
public static void main(String[] args) {
    String str = "Old Value";
    str = "New Value";
}
```

str →

"Old Value" → Garbage:
Will be removed from the
Memory by the Java Garbage Collector

"New Value"

```java
public static void main(String[] args) {
    String str1 = "Value1";
    String str2 = str1;
    str2 = "Value2";
}
```

str1 ⟶ "Value1"
str2 ⟶ "Value2"

Java: Program

scanner class : next() method

```java
public static void main(String[] args) {
    Scanner input = new Scanner(System.in);
    System.out.print("Enter your name: ");
    System.out.println("Your name is: " + input.next());
}
```

```
Kamal
Your name is Kamal
```

Methods: scanner class

```
input.next(); // Read a String
input.nextInt(); // Read an integer
input.nextDouble(); // Read a double

.nextByte(), .nextShort(), .nextLong(), .nextFloat(), .nextBoolean()

When one of these methods is called, the program will pause execution and
wait for the user to enter a value, the entered value will be returned by these
methods.

Note: we don't have .nextChar()
```

scanner class : nextInt() method

```java
package CSE1203;

import java.util.Scanner;

public class First {

public static void main(String[] args) {
Scanner scan=new Scanner(System.in);
int a=scan.nextInt();
int b=scan.nextInt();
int s=a+b;
System.out.println("sum="+s);
}
}
```

Here two integers input from keyboard stored in variable a and b. Then s stored sum of a & b

Built in Statements

If, switch, for, while,do-while are the same as C/C++l

Java: Program

Local Variable and its Scope

The scope of a variable is the part of the program where the variable can be referenced/used

- A variable defined inside a method is called a local variable.

- The scope of a local variable starts from its declaration and continues to the end of the block that contains the variable.

- A local variable must be declared and assigned a value before it can be used.

- Parameters are also local variables, their scope is the whole method.

Java: array declaration

```
dataType[] arr; (or)
dataType []arr; (or)
dataType arr[];
```

Java: array instantiation

```
arrayRefVar=new datatype[size];
```

Example: Local Variable

```java
package CSE1203;
public class First {

public static void main(String[] args) {
 if(true) {
   int i=5;
   System.out.println("i="+i);
  }
 System.out.println("i="+i);
}
```

Here error occurs at second println as i declared inside block if

Example: array

```java
package CSE1203;
public class First {

public static void main(String[] args) {
int[]  ax=new int[5];
ax[0]=10; ax[1]=20;
for(int i=0;i<5;i++)
 System.out.println(" "+ax[i]);
}
}
```

Java: Program

Example: array **pass by reference**

```java
public static void main(String[] args) {
    int[] numbers = {0, 1};
    change(numbers);
    printArray(numbers); // 1 0
}

public static void change(int[] numbers) {
    numbers[0] = 1; // {1, 1}
    numbers[1] = 0; // {1, 0}
}

public static void printArray(int[] numbers) {
    for(int i = 0; i < numbers.length; i++)
        System.out.print(numbers[i] + " ");
}
```

Here array is an object and it is passed by reference

Java: anonymous object

Anonymous means **Nameless**. An anonymous object is basically a value that has been created but has no name.

Example: anonymous object

```java
package CSE1203;
import java.awt.Point;
public class First {
 public static void main(String[] args) {
  Point p=getPoint();
  System.out.println("p="+p);
 }
 private static Point getPoint() {
 return new Point(1,2); //annonymous object
 }
}
```

Java: array of anonymous object

```java
package CSE1203;
import java.awt.Point;
public class First {
 public static void main(String[] args) {
  int[] numbers=getNumber();
  printArray(numbers);
 }
 public static void printArray(int[] numbers) {
   for(int i=0;i<numbers.length;i++)
   System.out.print(" "+numbers[i]);
 }
 public static int[] getNumber() {
   return new int[] {1,2,3,4,5};
 }
}
```

Java: Program

Java: Array class methods for

- Sorting
- Searching
- Comparing
- Filling
- Returning a string representation of an array

Java: Arrays sort() method

```java
package CSE1203;
import java.util.Arrays;

public class First {
 public static void main(String[] args) {
  int[] numbers= {10,20,70,90,30,80};
  System.out.println("Initial Array:");
  printArray(numbers);
  Arrays.sort(numbers);
  System.out.println("\nSorted Array:");
  printArray(numbers);
}
 private static void printArray(int[] numbers) {
  for(int i=0;i<numbers.length;i++)
    System.out.print(" "+numbers[i]);
}
}
```

Java: Arrays BinarySearch() method

```java
package CSE1203;
import java.util.Arrays;
public class First {
 public static void main(String[] args) {
  int[] numbers= {10,20,70,90,30,80};
  System.out.println("Initial Array:");
  printArray(numbers);
  Arrays.sort(numbers);
  System.out.println("\nSorted Array:");
  printArray(numbers);
  int i=Arrays.binarySearch(numbers, 44);
  //returns index or if not found returns -ve number
  System.out.println("\nIndex of found element="+i);
}
 private static void printArray(int[] numbers) {
  for(int i=0;i<numbers.length;i++)
    System.out.print(" "+numbers[i]);
}
}
```

Java: Arrays fill() method

```java
// fill(array, value): fill whole array
int[] numbers1 = new int[8]; // {0, 0, 0, 0, 0, 0, 0, 0}
Arrays.fill(numbers1, 3); // {3, 3, 3, 3, 3, 3, 3, 3}

// fill(array, fromIndex, toIndex, value)
int[] numbers2 = new int[8]; // {0, 0, 0, 0, 0, 0, 0, 0}
Arrays.fill(numbers2, 3, 7, 5); // {0, 0, 0, 5, 5, 5, 5, 0}
```

Java: Program

Java: **A**rrays toString() method

```java
package CSE1203;
import java.util.Arrays;
public class First {
 public static void main(String[] args) {
  int[] ax= {10,20,70,90,30,80};
  System.out.println("Initial Array:");
  System.out.println(Arrays.toString(ax));
 }
}
```

Output

```
Initial Array:
[10, 20, 70, 90, 30, 80]
```

Note: The **toString()** method returns the String representation of the object. By overriding the **toString()** method of the Object class, we can return values of the object, so we don't need to write much code.

Java: Variable Length Parameter(…)

```java
package CSE1203;
import java.util.Arrays;
public class First {
 public static void main(String[] args) {
    int[] ax= {10,20,70,90,30,80};
    System.out.println(sum(1,2,3));
    System.out.println(sum(1,2,3,4));
    System.out.println(sum(ax));
 }
 public static int sum(int...ax) {
    int s=0;
    for(int i=0;i<ax.length;i++)
    s=s+ax[i];
    return s;
 }
}
```

Java: 2D array Declaration

```java
int[][] numbers; // null

numbers = new int[5][3];
```

Java: Program

Java: ArrayList class

```
ArrayList<Integer> integers; // null
integers = new ArrayList<>();

ArrayList<Integer> integers = new ArrayList<>();
ArrayList<String> fruits = new ArrayList<>();
ArrayList<Double> doubles = new ArrayList<>();
```

⚠ In an ArrayList, we can store objects (String, Integer, Boolean, Double, Character,...), not a primitive type (int, boolean, double, char...).

Note: The **ArrayList** class is a resizable/ variable length array. It includes methods **add(), set(), remove(), size(), clear()** etc.

Note: To display the content of an array, it should be written inside the print() method. To write toString() method after array object is not mandatory

```
for ( TYPE VAR_NAME : ArrayList/Array ) {
    ...
}
```

– In each iteration, the variable VAR_NAME will hold the value of an element inside the ArrayList/Array, starting from the first element.

– There is no index

– Safe (Boundaries)

Example: ArrayList class

```
package CSE1203;
import java.util.ArrayList;
import java.util.Arrays;
public class First {
public static void main(String[] args) {
ArrayList<String> fruits=new ArrayList<>();
fruits.add("Apple");//insert at back
fruits.add("Mango");//insert at back
fruits.add("Orange");//insert at back
System.out.println(fruits);
fruits.add(0,"Banana");//insert at index 0
System.out.println(fruits);
System.out.println(fruits.get(0)); //get element
of index 0
fruits.set(1, "Guava"); //change value at index 1
System.out.println(fruits);
fruits.remove(2); //delete value at index 2
System.out.println(fruits);
fruits.remove("Orange"); //delete by value
System.out.println(fruits.toString()); //same
System.out.println(fruits.size()); //Total
elements
fruits.sort(null); //sort elements
Collections.sort(fruits);  //Alternative sort
fruits.clear(); //delete all elements
System.out.println(fruits);
}
}
```

Java: Program

```
for ( TYPE VAR_NAME : ArrayList/Array ) {
    ...
}
```

– In each iteration, the variable VAR_NAME will hold the value of an element inside the ArrayList/Array, starting from the first element.

– There is no index

– Safe (Boundaries)

Example: for-each loop

```java
package CSE1203;
import java.util.ArrayList;
import java.util.Arrays;

public class First {
 public static void main(String[] args) {
  ArrayList<String> fruits=new ArrayList<>();
  fruits.add("Orange");//insert at back
  fruits.add("Mango");//insert at back
  fruits.add("Apple");//insert at back
  for(String i:fruits)
  System.out.print(" "+i);
 }
}
```

Java: class & object

```
package CSE1203;
import java.awt.Point;

public class First {

public static void main(String[] args) {
  Circle c1=new Circle(new Point(4,2),3);
  System.out.println("Center="+c1.getCenter());
  System.out.println("Area="+c1.Area());
}
}
```

Note: here new Point(4,2) is anonymous object. Class Circle can be define in the same file with main() or in the different file.

```
package CSE1203;

import java.awt.Point;

class Circle{
Point c;
int r;
public
Circle(Point c,int r){
 this.c=c;
 this.r=r;
}
double Area() {
return 2*3.14*r;
}
Point getCenter() {
return c;
}
}
```

Java: static variable/method

Static variables and static methods belong to the class, they are shared between all objects

– If an object modifies a static variable, all objects of the same class are affected.
– A static variable can be accessed without creating an instance of the class.
– A static method can be called using the same way.
– A static method can not access instance variables or methods.

```java
package CSE1203;
import java.awt.Point;

public class First {

public static void main(String[] args) {
Circle c1=new Circle(new Point(4,2),3);
Circle c2=new Circle(new Point(1,2),4);
System.out.println("Center="+c1.getCenter());
System.out.println("Area="+c1.Area());
System.out.println("Circle
Count="+c1.getCount());
}
}
```

```java
package CSE1203;
import java.awt.Point;

class Circle{
Point c;
int r;
static int count=0;
public
Circle(Point c,int r){
 this.c=c;
 this.r=r;
 count++;
}
double Area() {
return 2*3.14*r;
}
Point getCenter() {
return c;
}
static int getCount() {
return count;
}
}
```

Note: here count is a static variable and it is common for all objects. To return a static variable a static method is used.

Java: static variable/method

Java: Visibility Modifiers

Visibility modifiers can be used to specify the visibility of a class and its members

– public: Can be used on classes and class members. Used for unrestricted access, i.e. can be accessed from any other class.
– private: Can be used on class members. Used for restricting the access to the defining class, i.e. can be accessed within the class only.
– protected

– If no visibility modifier is used, then by default the classes, methods, and data fields are accessible by any class in the same package.

Example: Visibility Modifiers

```
package CSE1203_01

class C1 {
    C2 c2; // can access C2
    C3 c3; // can access C3
}

public class C2 {
    C1 c1; // can access C1
    C3 c3; // can access C3
}
```

```
package CSE1203_02

public class C3 {
    C2 c2; // can access C2
    // can not access C1
}
```

Note: public class can be access from any package but default class can be accessed within the package

Java: Inner class

In Java, inner class refers to **the class that is declared inside class or interface.** Inner classes are **a security mechanism in Java**. We know a class cannot be associated with the access modifier private, but if we have the class as a member of other class, then the inner class can be made private. And this is also used to access the private members of a class.

```
package CSE1203;
public class First {
public static void main(String[] args) {
    //outer is Outer class object
    Outer outer=new Outer();
    outer.Display();
    //in is Inner class object
    Outer.Inner in = new Outer().new Inner(45);
    in.getY();
}
}
```

Note: Here object of private Inner class is created via public Outer class. Outer class private members can be accessed by inner class

Java: static variable/method

```java
package CSE1203;

import java.awt.Point;

public class Outer{
private int x;
class Inner{
private int y;
public Inner(int y) {
this.y=y;
}
public void setY(int y) {
this.y=y;
}
public int getY() {
return y;
}

}
public void Display() {
Inner inner=new Inner(0);
inner.setY(12);
System.out.println(inner.getY());
}
}
```

```java
package CSE1203;
public class First {

public static void main(String[] args) {
//outer is Outer class object
Outer outer=new Outer();
outer.Display();
//in is Inner class object
Outer.Inner in = new Outer().new Inner(45);
in.sum();
}
}
```

```java
package CSE1203;

public class Outer{
private int x=20;
class Inner{
private int y;
public Inner(int y) {
this.y=y;
}
public void setY(int y) {
this.y=y;
} public int getY() {
return y;
}
```

```java
public void sum() {
System.out.println("inside sum="+(x+y));
}
}
public void Display() {
Inner inner=new Inner(0);
inner.setY(12);
System.out.println(inner.getY());
}
}
```

Java: inheritance

```
package CSE1203;

class Calculator{
    int s;
    public int add(int x,int y) {
        s=x+y;
    return s;
    }
    public int aub(int x,int y) {
        s=x-y;
    return s;
    }
}
public class First extends Calculator {
  public static void main(String[] args) {
    First cal=new First();
    System.out.println(cal.add(3, 5));
}
}
```

Note: while defining multiple classes in a single Java file you need to make sure that only one class among them is public. If you have more than one public classes a single file a compile-time error will be generated.
Use extends keyword after class definition for inheritance

1. super can be used to refer immediate parent class instance variable.
2. super can be used to invoke immediate parent class method.
3. super() can be used to invoke immediate parent class constructor.

```
package CSE1203;
class Human{
String name="Human";
}
class Person extends Human{
String name="Person";
}
class Employee extends Person{
String name="Employee";
public void Display() {
    System.out.println(name);
    System.out.println(super.name);
}
}
public class First {
public static void main(String[] args) {
Employee emp=new Employee();
emp.Display();
}
}
```

Java: inheritance

Java: `super method`

```
package CSE1203;
class Person{
String name="Person";
public void Display() {
  System.out.println(name);
}
}

class Employee extends Person{
String name="Employee";

public void Display() {
  super.Display();
  System.out.println(name);
}
}
public class First {
public static void main(String[] args) {
Employee emp=new Employee();
emp.Display();
}
```

Note: Here using super, parent class method Display() is called.

Java: uses of `super` keyword

1. super can be used to refer immediate parent class instance variable.
2. super can be used to invoke immediate parent class method.
3. super() can be used to invoke immediate parent class constructor.

```
package CSE1203;
class Human{
String name="Human";
}
class Person extends Human{
String name="Person";
}
class Employee extends Person{
String name="Employee";
public void Display() {
  System.out.println(name);
  System.out.println(super.name);
}
}
public class First {
public static void main(String[] args) {
Employee emp=new Employee();
emp.Display();
}
}
```

Java: inheritance

Java: `super() method`

```java
package CSE1203;
class Person{
String name="Person";
public Person() {
  System.out.println(name);
}
public Person(String s) {
  name=s;
  System.out.println(name);
}
}
class Employee extends Person{
String name="Employee";
public Employee() {
  super("Rana");
  System.out.println(name);
}
}
```

1. super can be used to refer immediate parent class instance variable.
2. super can be used to invoke immediate parent class method.
3. super() can be used to invoke immediate parent class constructor.

is called when child class object is created. If we want to call parameterized constructor then super(values) is used as the first statement inside the child constructor.

Java: `abstract class`

- A class which contains the **abstract** keyword in its declaration is known as abstract class.

- Abstract classes may or may not contain abstract methods ie., methods with out body (public void get();)

- But, if a class have at least one abstract method, then the class **must** be declared abstract.

- If a class is declared abstract it cannot be instantiated.

- To use an abstract class you have to inherit it from another class, provide implementations to the abstract methods in it.

```java
package CSE1203;
abstract class Shape{
String name="Shape";
public abstract void Display();
}
class Circle extends Shape{
String name="Circle";
public void Display() {
System.out.println("in class "+name);
}
}
public class First {
public static void main(String[] args) {
Circle c=new Circle();
c.Display();
}
}
```

Java: inheritance

Java: `abstract class`

Notes on prev program: In Shape class an abstract method is declared but its implementation is done in Circle class. Here Shape class must be abstract as an abstract method in it. However an abstract class may or may not have abstract method. As Shape is an abstract class no object is created of that class.

Java: `interface`

An **interface in Java** is a blueprint of a class. It has static constants and abstract methods.
The interface in Java is *a mechanism to achieve abstraction*.
There can be only abstract methods in the Java interface, not method body. It is used to achieve abstraction and multiple inheritance in Java.
In other words, you can say that interfaces can have abstract methods and variables. It cannot have a method body.
Abstraction is a process of hiding the implementation details and showing only functionality to the user.

- Like **abstract classes**, interfaces **cannot** be used to create objects
- Interface methods do not have a body - the body is provided by the "implement" class
- On implementation of an interface, you must override all of its methods
- Interface methods are by default `abstract` and `public`
- Interface attributes are by default `public`, `static` and `final`
- An interface cannot contain a constructor (as it cannot be used to create objects)

Java: `multiple nterface`

```java
package CSE1203;
interface FI{
  public void myMethod(); // interface method
 }
interface SI {
  public void myOtherMethod(); // interface method
 }
class DemoClass implements FI, SI {
public void myMethod() {
 System.out.println("From FI");
}
public void myOtherMethod() {
System.out.println("From SI");
}
}
public class First {
public static void main(String[] args) {
DemoClass myObj = new DemoClass();
    myObj.myMethod();
    myObj.myOtherMethod();
}
}
```

Notes Two interfaces FI and SI are implemented in DemoClass and there achieving multiple inheritance. Multiple inheritance is only achieved by the interface not by the class

Java: inheritance

## Java: `interface example`

```
package CSE1203;
interface FI{
  public void myMethod(); // interface method
 }
interface SI {
  public void myOtherMethod(); // interface method
 }
class DemoClass implements FI, SI {
public void myMethod() {
 System.out.println("From FI");
}
public void myOtherMethod() {
System.out.println("From SI");
}
}
public class First {
public static void main(String[] args) {
DemoClass myObj = new DemoClass();
    myObj.myMethod();
    myObj.myOtherMethod();
}
}
```

Notes Two interfaces FI and SI are implemented in DemoClass and there achieving multiple inheritance. Multiple inheritance is only achieved by the interface not by the class

Java: `abstact class vs interface`

Abstract class	Interface
1) Abstract class can **have abstract and non-abstract** methods.	Interface can have **only abstract** methods. Since Java 8, it can have **default and static methods** also.
2) Abstract class **doesn't support multiple inheritance**.	Interface **supports multiple inheritance**.
3) Abstract class **can have final, non-final, static and non-static variables**.	Interface has **only static and final variables**.
4) Abstract class **can provide the implementation of interface**.	Interface **can't provide the implementation of abstract class**.
5) The **abstract keyword** is used to declare abstract class.	The **interface keyword** is used to declare interface.
6) An **abstract class** can extend another Java class and implement multiple Java interfaces.	An **interface** can extend another Java interface only.
7) An **abstract class** can be extended using keyword "extends".	An **interface** can be implemented using keyword "implements".
8) A Java **abstract class** can have class members like private, protected, etc.	Members of a Java interface are public by default.
Relation between class & interface
